

# End-to-end QoS control for Triple Play services in converged networks

# Evolution of networks

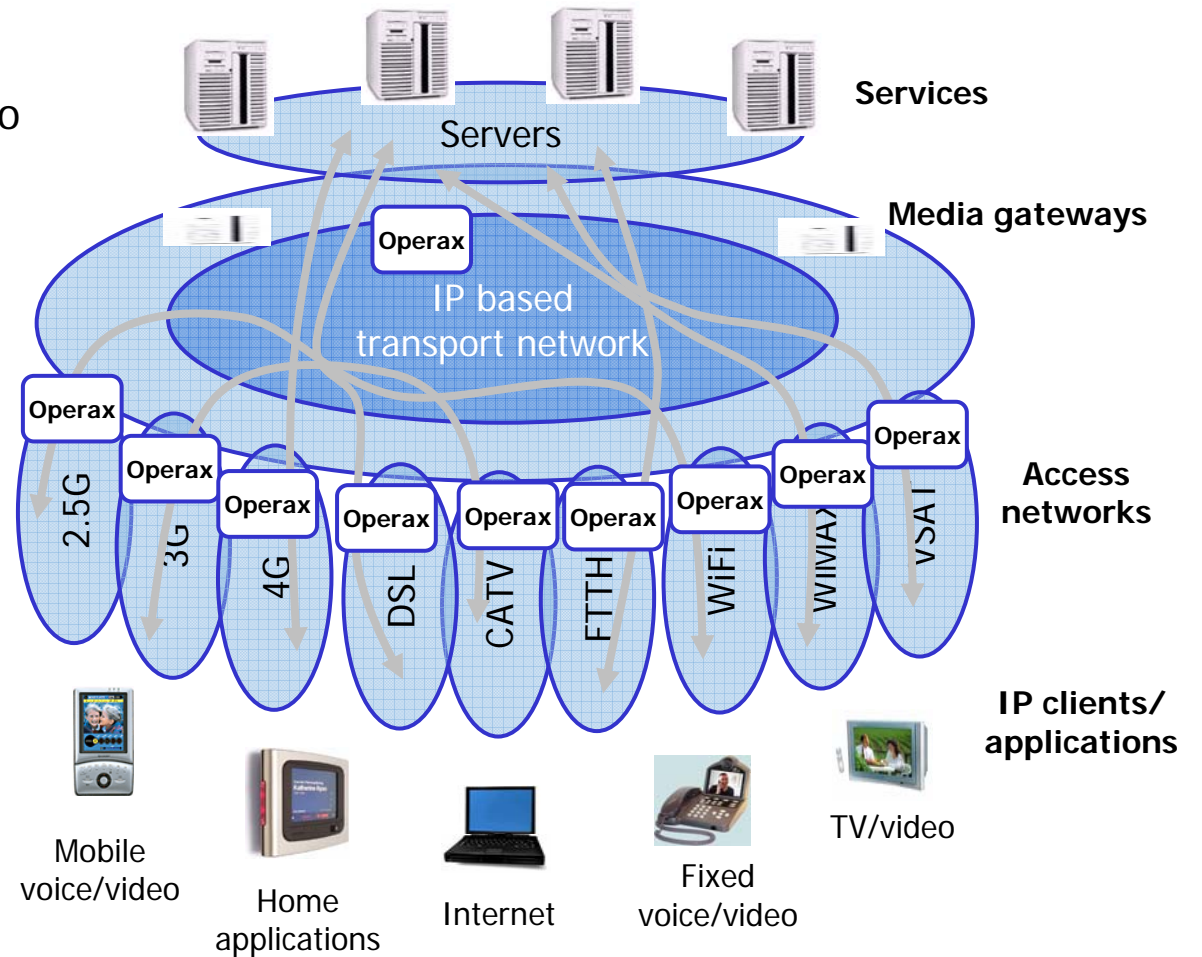

## Operax solution

- ▶ Network resource control to guarantee QoS end-to-end
- ▶ Enables profitable multi-service IP networks

## Operax vision

Guarantee QoS end-to-end:

- ▶ multi-service,
- ▶ multi-technology,
- ▶ multi-vendor,
- ▶ in a cost efficient way!

**Operax** NRC component

↔ Ensured IP traffic

# Operax products and solutions

---

**Operax Triple Play**

– Broadband VAS

**Operax Bandwidth Manager**

– Multi-Service NGN

# Network resource control concept

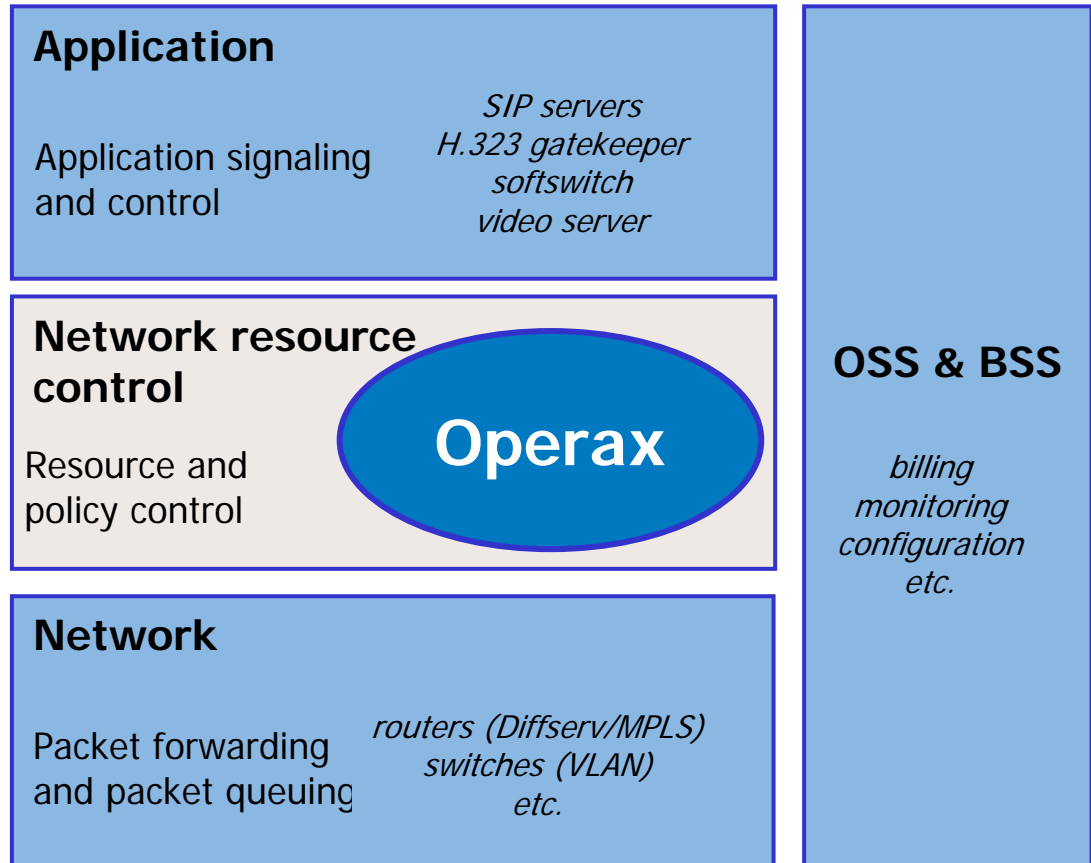

NRC solution for both access and core

Server based software solution (Linux, Solaris)

Real-time admission control (policy- and network resource based) for applications, user sessions and traffic aggregates

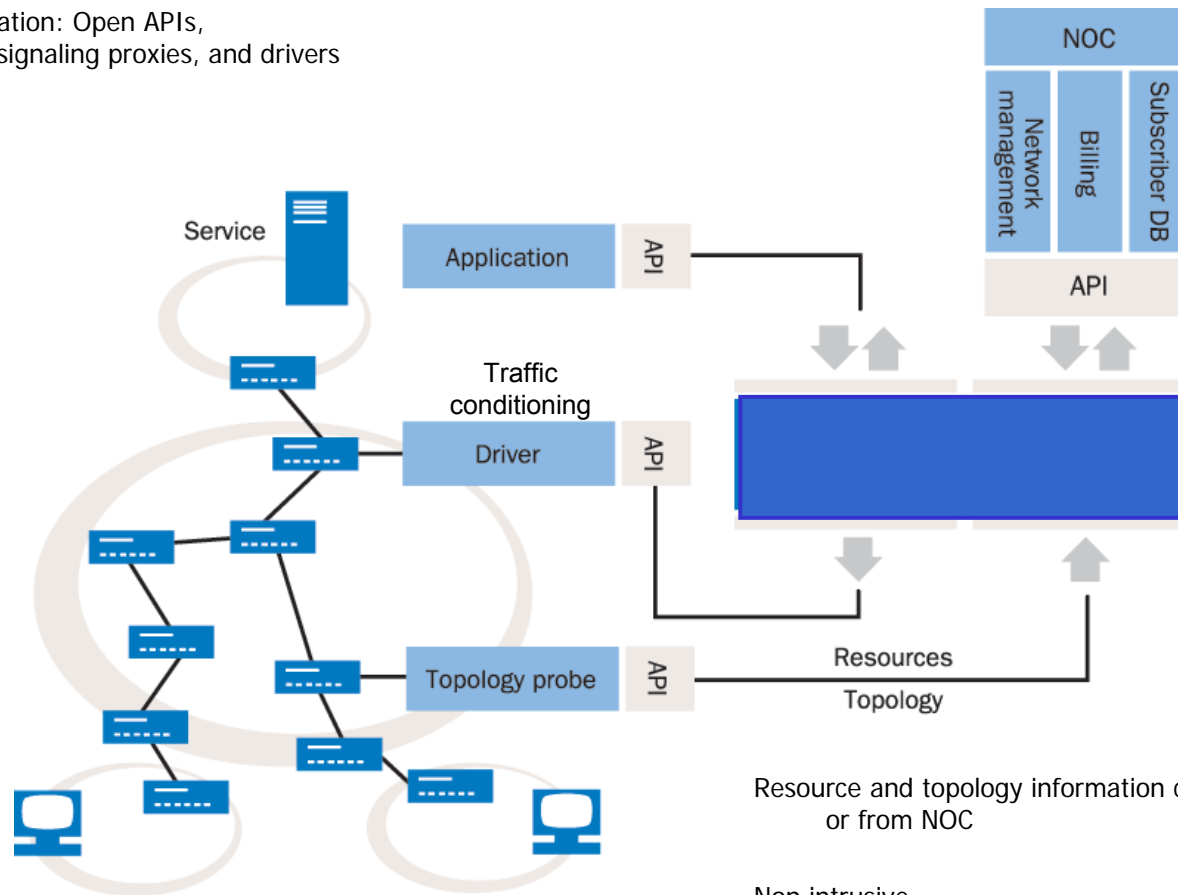

Complements traditional provisioning and management tools

Output CDR's and statistics to OSS

# Operax NRC operation and integration

Integration: Open APIs,  
signaling proxies, and drivers

# Operax Triple Play

---

## Network Resource Control in Broadband Access Networks

- ▶ Policy Control
- ▶ Resource Control
- ▶ Layer 2/3
  - ATM
  - Ethernet
  - IP/MPLS

Network topology aware  
Resource map in memory

## Northbound interface

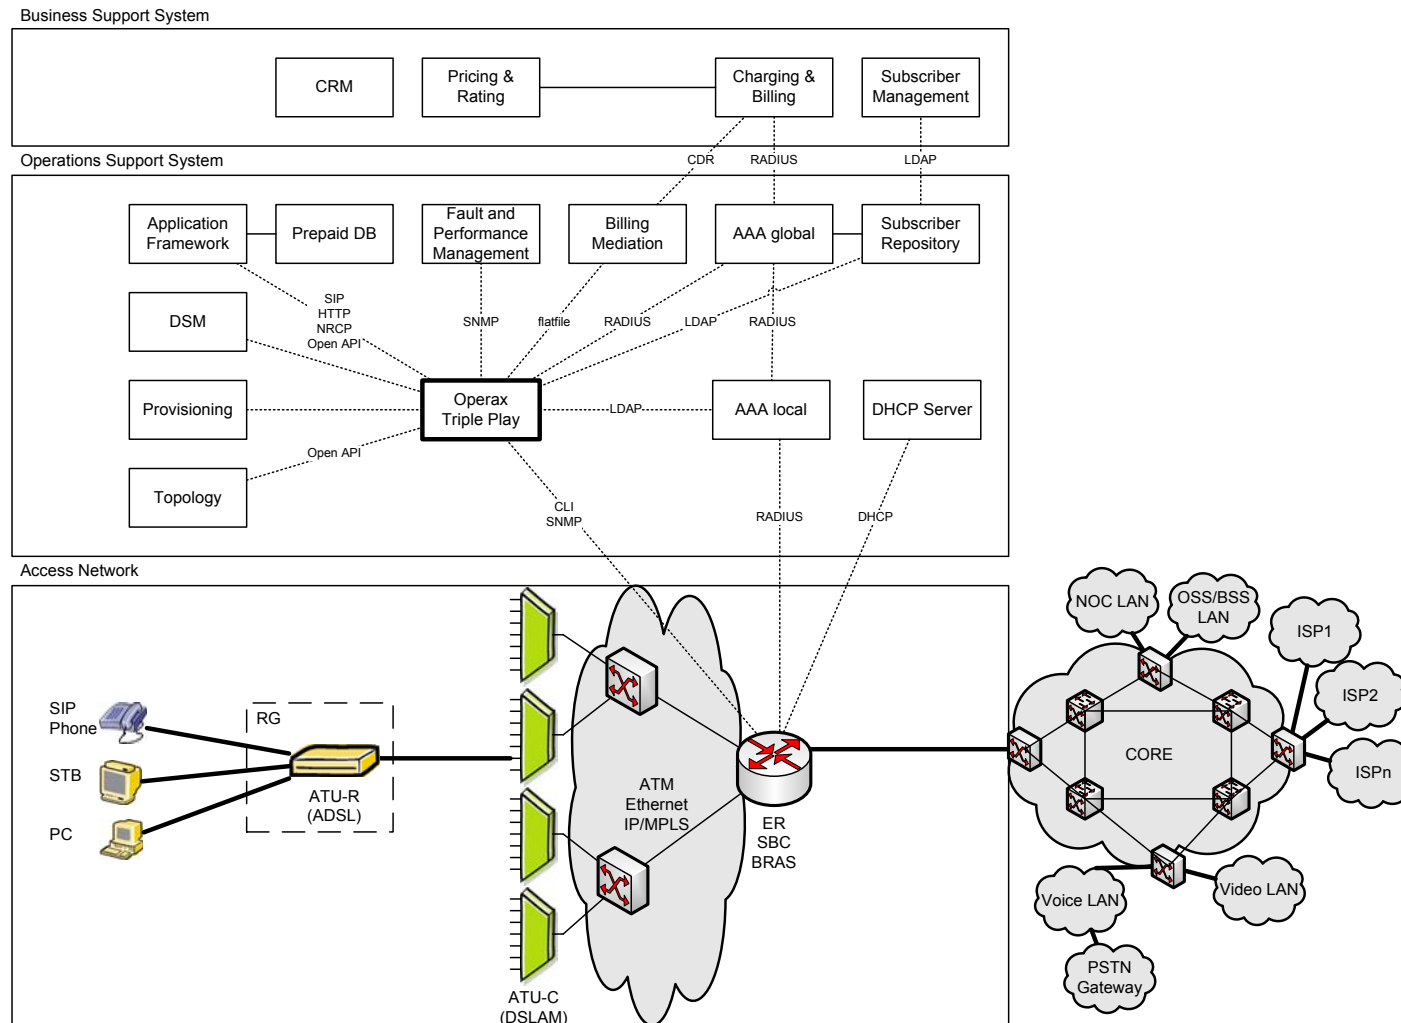

- ▶ Resources requests forwarding from the network. Preferably via AF

## Path-sensitive admission control

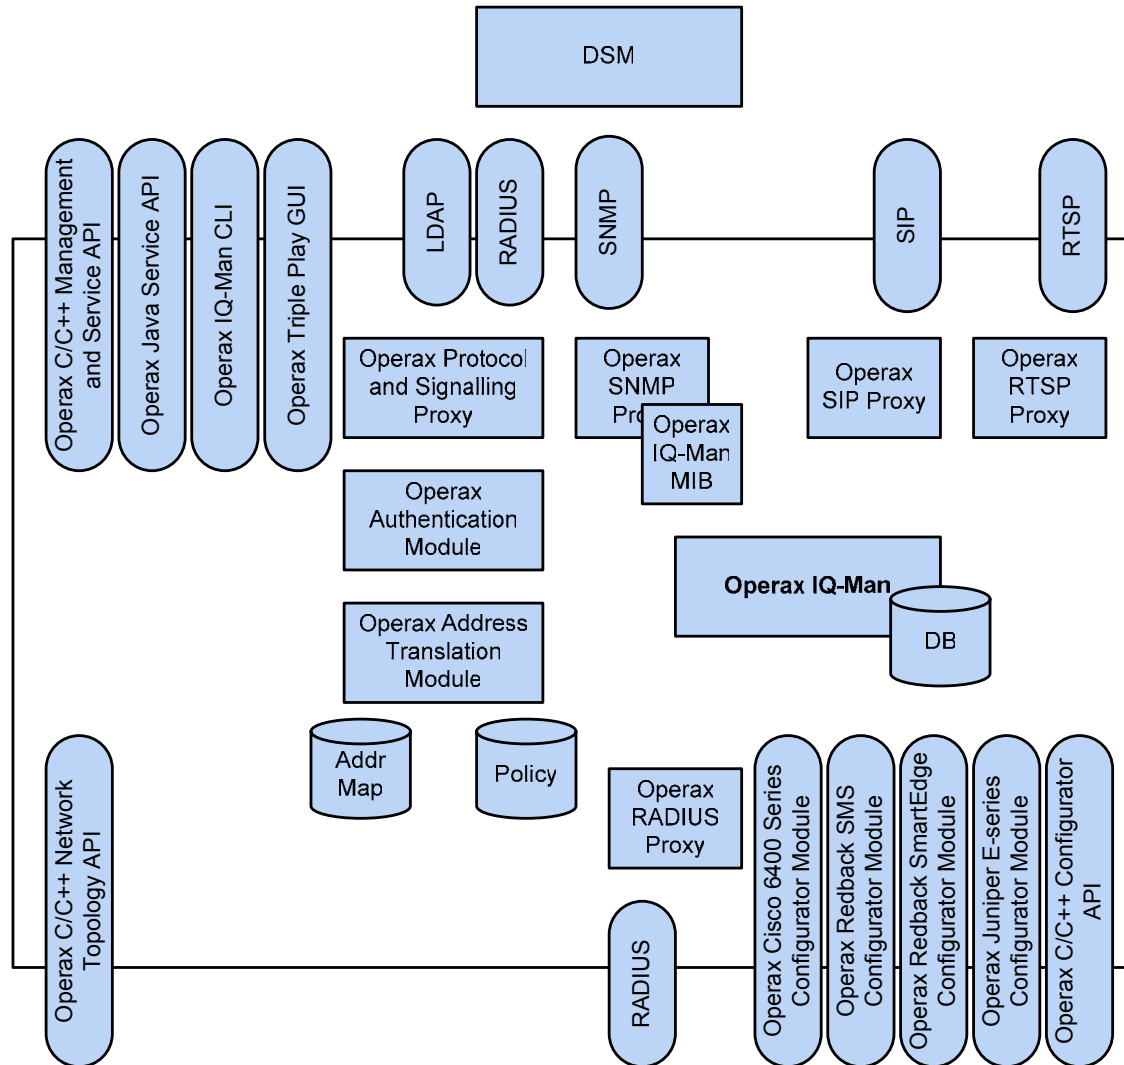

- ▶ Resource requests evaluated at each link

# Operax Triple Play

## Product in target environment

# Operax Triple Play Product Architecture

## Access network topology

---

Typically managed/inserted in Operax Triple Play

- ▶ by integration with OSS using the Network Topology API
- ▶ by using topology file

Layer 2 topology

- ▶ ATM topology + VC/VP
- ▶ Ethernet topology + VLAN
- ▶ etc.

Topology representation by using “virtual” IP addresses

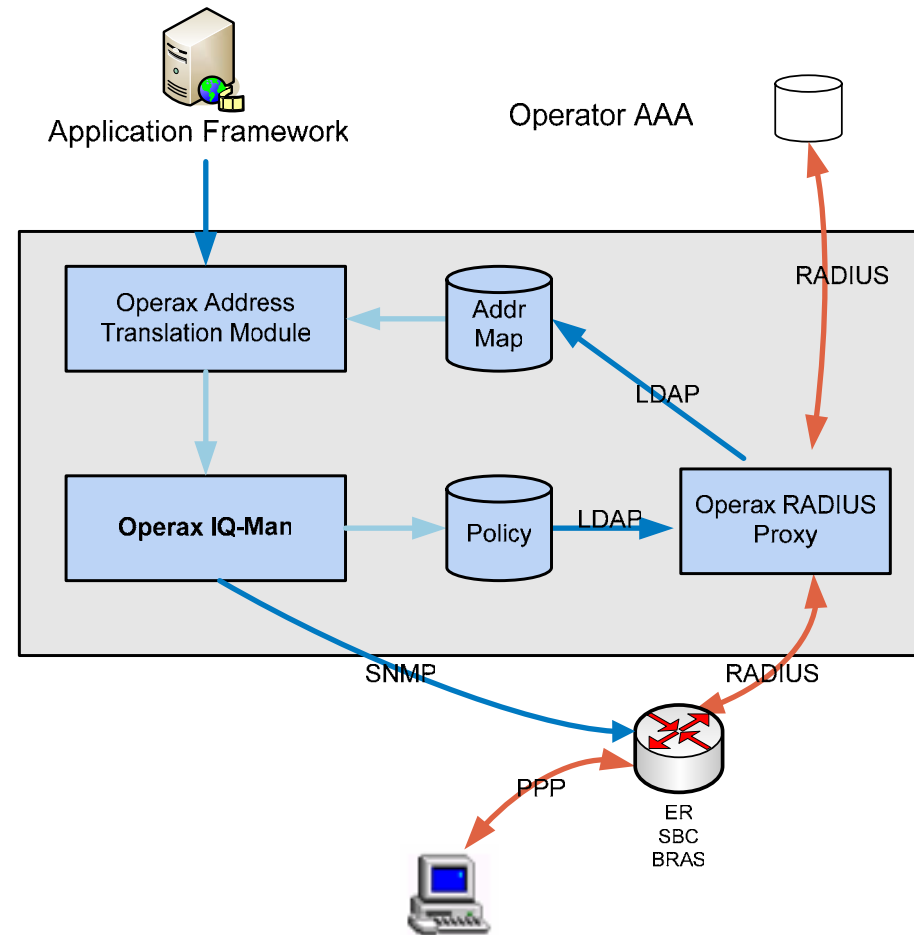

# Operax Address Translation Module

Rewrite dynamic addresses to static physical addresses

Use LDAP database

- ▶ populated by RADIUS

Cache of IP addresses (expire after a configurable amount of time)

---

# Application framework integration

## **NRCP, Network Resource Control Protocol**

---

Bandwidth requests may be issued by application servers, call managers, other BMs, etc.

On protocol-level a long-lived secured connection is maintained

- ▶ streaming of request/replies possible

Hard or soft (time-limited) state for bandwidth reservations

## **NRCP, Basic bandwidth request**

---

**Requested rate (preferred and optional minimum)**

**Network service class (index)**

- ▶ To be defined separately (e.g., conversational, streaming, interactive, background)

**Source/ingress address (prefix)**

- ▶ determines where the reservation starts

**Destination address (prefix)**

- ▶ determines where the reservation ends (The NRC can figure out the egress of its domain and ingress of next domain)

**Optional Start/Stop time**

- ▶ For advance reservations and soft state

**Etc.**

## Custom integration via Open API

---

- ▶ VoD integration points
  - Middleware
  - RTSP Server
- ▶ VoIP integration points
  - SBC
  - SIP call server/agent
- ▶ Other AF enabling network forwarding resources to subscribers
  - Gaming portals

# Operax SIP Proxy

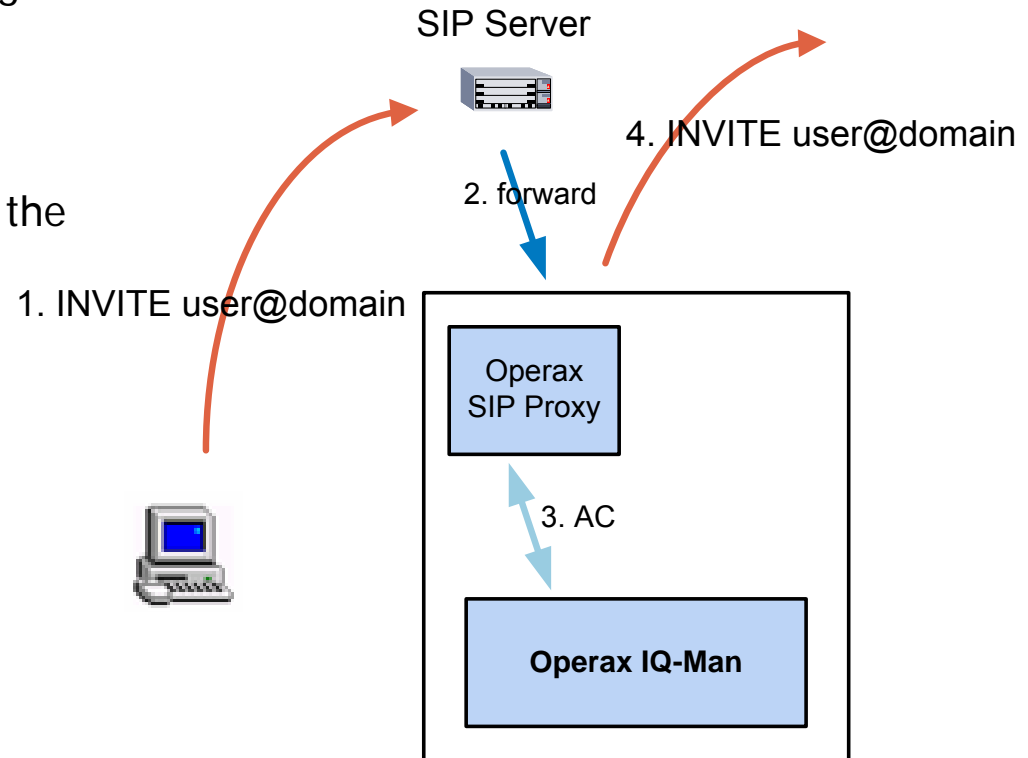

QoS for sessions established using SIP  
Single- or two-phase setup

- ▶ Reserve
- ▶ Commit

Added in SIP signaling path after the main SIP Server

Reservation based on SDP

# Operax RTSP Proxy

QoS handling, resource reservation

Hide media servers behind the RTSP proxy

- ▶ Available media servers are configured into RTSP Proxy

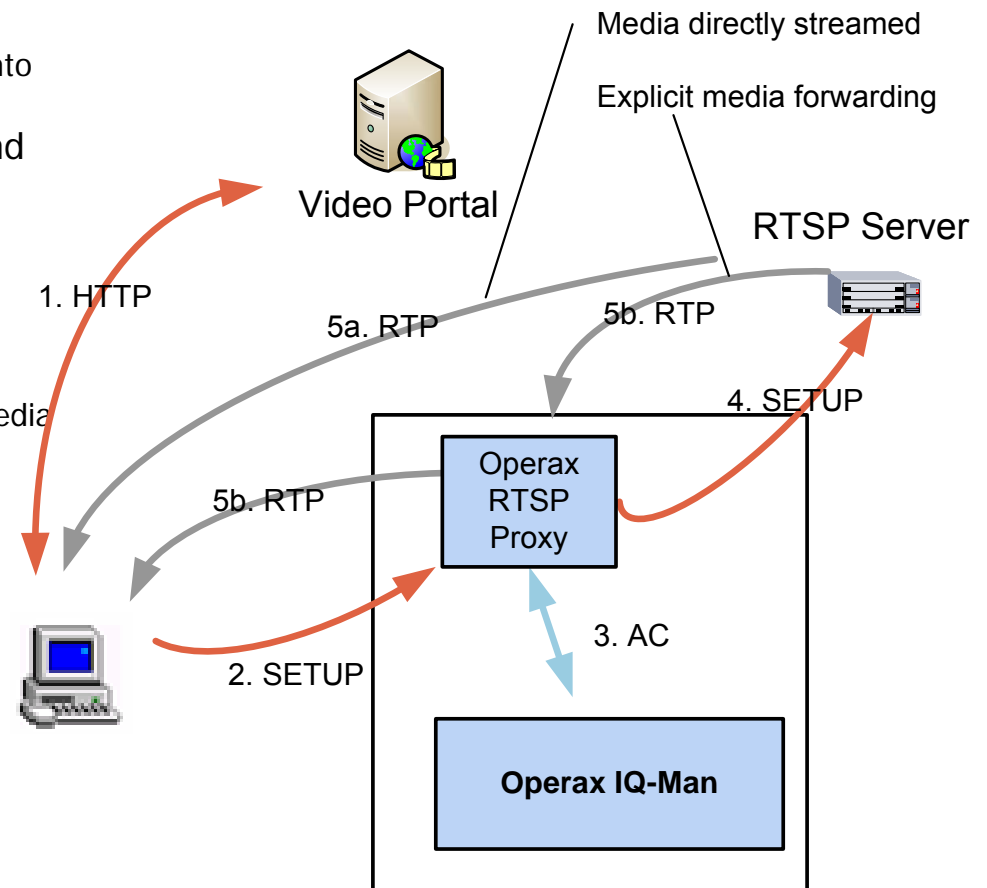

Intermediate unit between an RTSP client and an RTSP server

Modes of configuration

- ▶ Media directly streamed
- ▶ Explicit media forwarding

Load balancing

- ▶ Choosing one of a number of possible media servers

---

# Traffic conditioning (policy enforcement)

## Generic top-down traffic conditioning API

---

Packet filter

address ranges, port ranges, DSCP, protocol

Token bucket parameters

Marker

To be applied to edge routers, CPEs etc.

In line with ETSI/ITU/MSF

# BRAS through Operax RADIUS Proxy

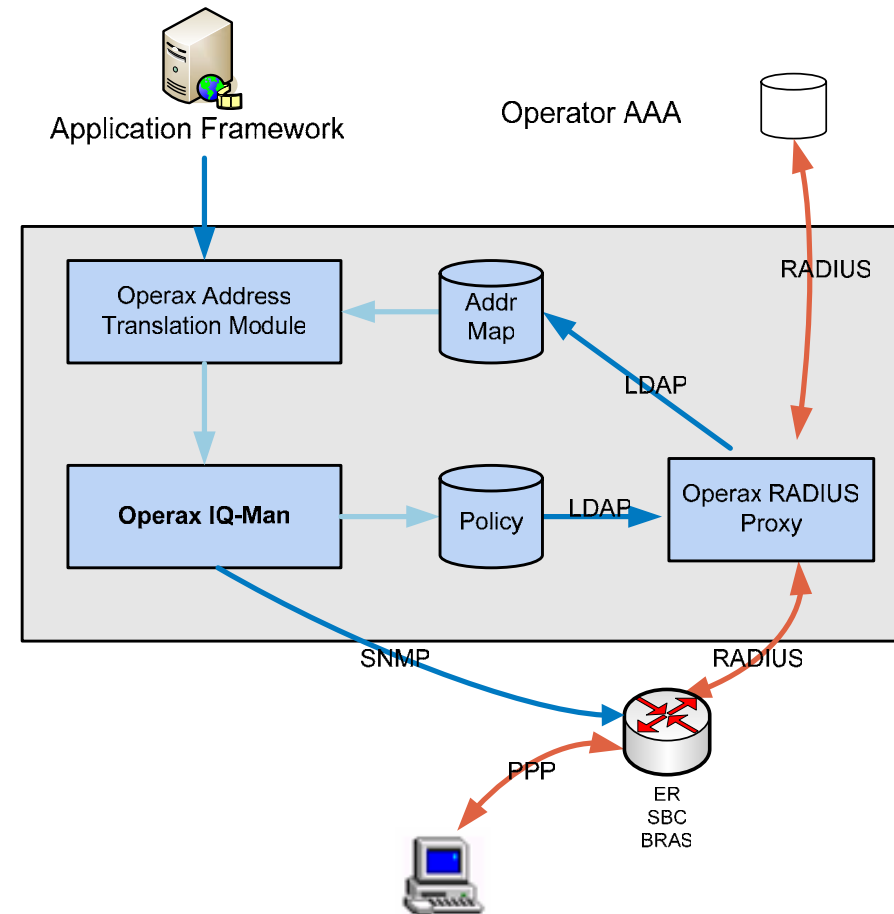

Operators choices:

- ▶ Operax RADIUS proxy
- ▶ Application Specific Module (ASM) installed in already deployed local AAA Proxy

Provides functionality to:

- ▶ Get IP to physical address mapping (RADIUS-ACCT)
- ▶ Populate RADIUS-AUTH messages (VSAs) and thereby updating the policy for the subscriber

## Session Border controller

---

Combines session control and traffic conditioning

Session Control

SIP, RTSP,

Outsourcing admission decision to NRC using NRCP

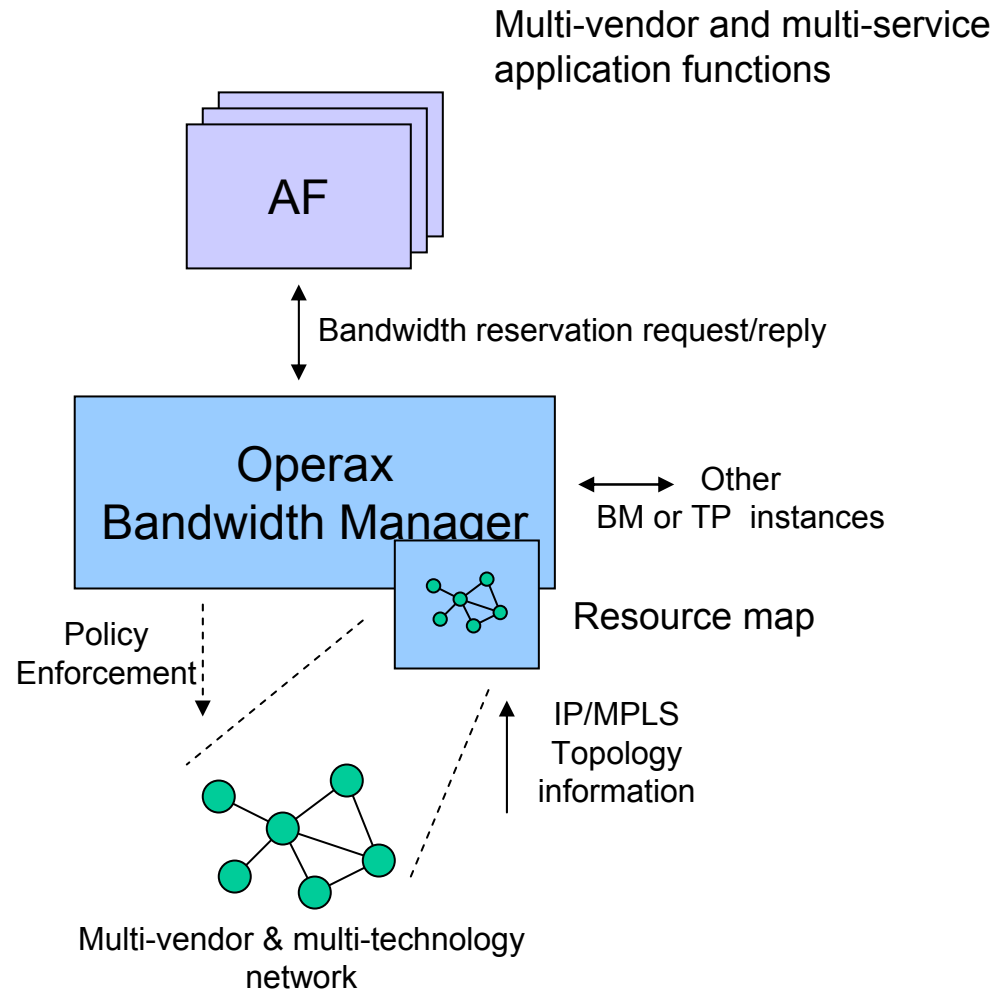

Activating traffic conditioning according to the response

---

# OPERAX BANDWIDTH MANAGER

# Operax Bandwidth Manager

## A multi-service QoS control system

Unified control for any service

Application driven call and connection admission control

Fine-grained network modeling and admission control

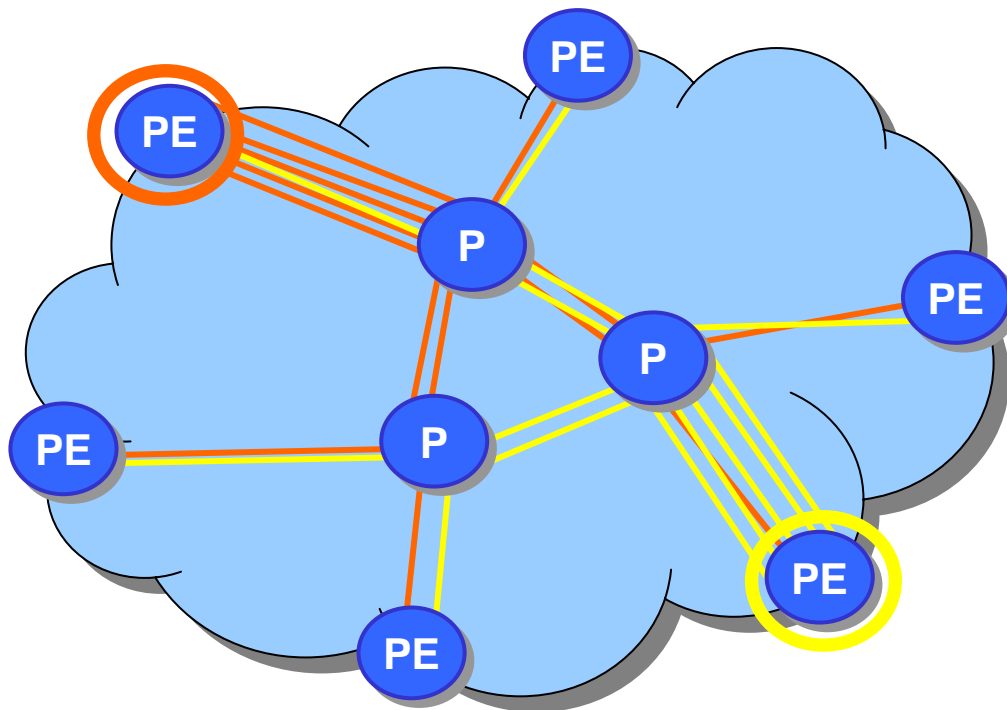

QoS guarantee end-to-end (access, metro, core)

Open and standardized interfaces

Distributed & hierarchical solution provides carrier grade reliability and performance

# Popular MPLS approach

## Long thin pipes

- ▶ Edge to edge tunnels
- ▶ Explicit bandwidth allocations
- ▶ Full mesh
- ▶ *Long thin pipes - tunnel LSPs*
- ▶  $N * (N - 1)$  LSPs

### Example case ( $N=100$ )

- ▶  $100 * (100 - 1) = 9\,900$  tunnel LSPs
- ▶ Single service
- ▶ Without protection

### Volume of entities to manage and resource partitioning grows with

- ▶ Network size (to the power of 2)
- ▶ Number of services (linear)
- ▶ Protection (linear)

# Ideal approach

## Hop-by-hop admission control

- ▶ Class based forwarding in core
- ▶  $k * N$  hops to manage

### Example case ( $N=100, k=5$ )

- ▶  $100 * 5 = 500$  interfaces
- ▶ Multi-service
- ▶ Protection included

### Volume of entities to manage grows with

- ▶ Network size (linear with "connectivity")

LSPs used only for addressing, separation and protection purposes through network. No static resource reservation per LSP.

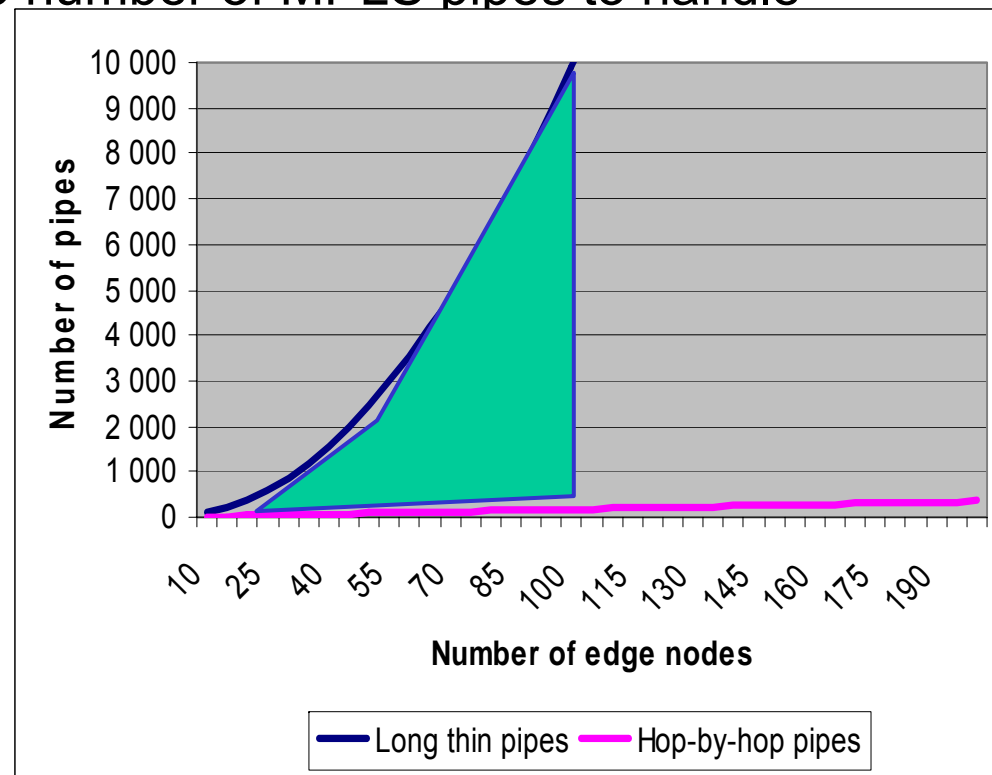

# Planning, design and administration of MPLS pipes

Work load is proportional to number of MPLS pipes to handle

→ Long thin pipes grows quadratic with the number of edge nodes  $n(n-1)$

→ Hop-by-hop model grows linear with the number of edge nodes  $n$

**How big a network can the Operator handle?**

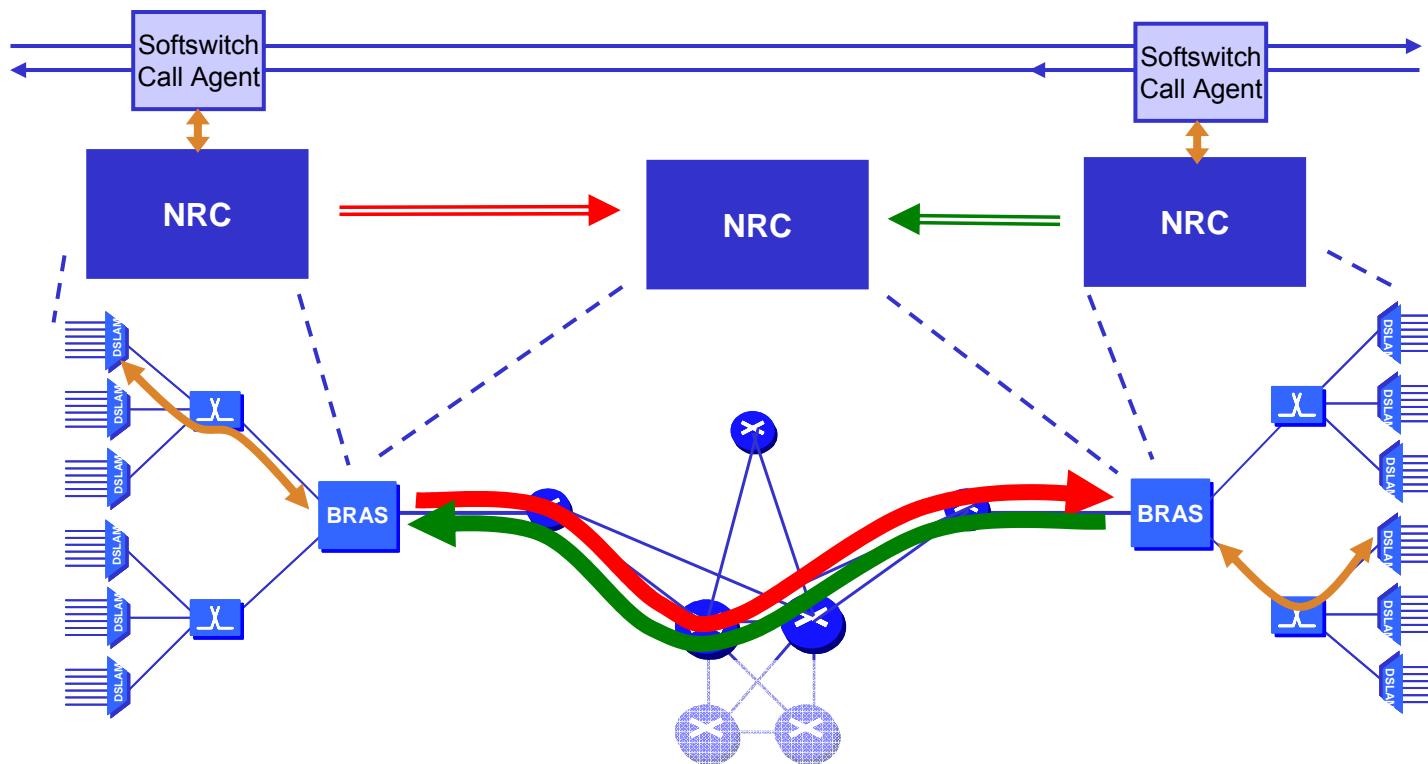

---

## End-to-end and inter-domain

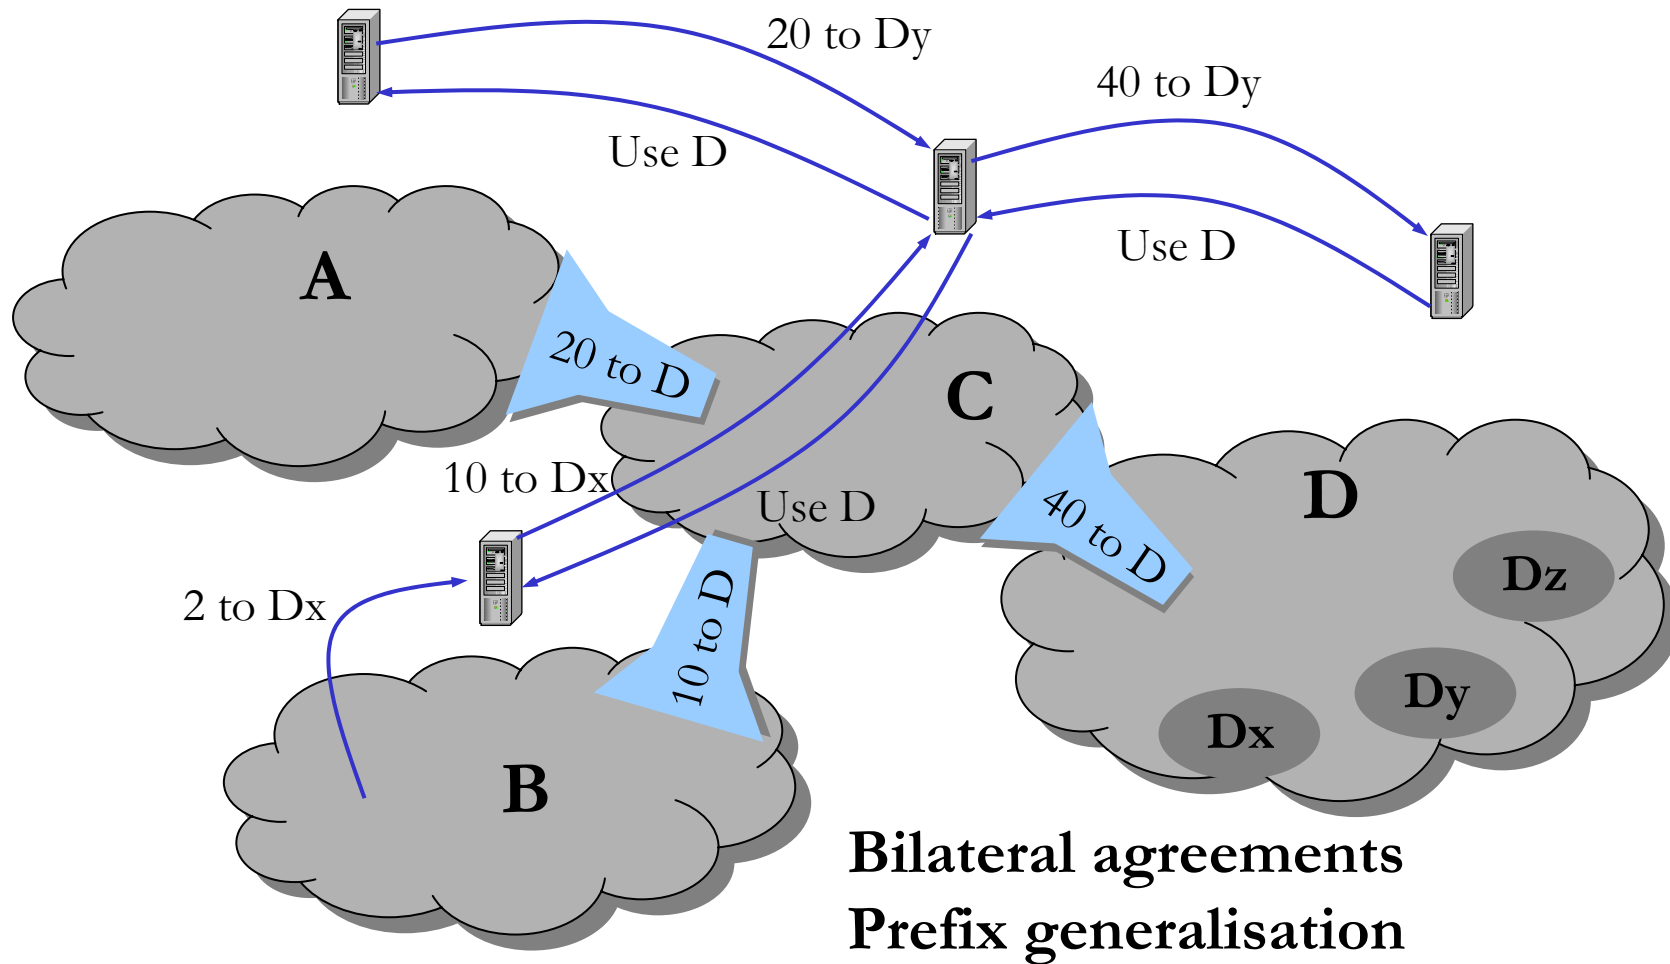

# Scalability through aggregation

High performance CAC through dynamic resource subscriptions

- ▶ Access NRCs can dynamically subscribe to shared resources
- ▶ Shared backbone resources are managed by a core NRC
- ▶ Reservations for individual calls involve access NRCs only

# Inter-domain core NRC and aggregation

## Inter-domain operation

---

Peering relations between neighboring NRC instances are configured

- ▶ compare configuration of BGP peering

NRC participates in IBGP

- ▶ to obtain the routes advertised by adjacent BGP domains
- ▶ To find the correct ingress point of adjacent domain for resource requests

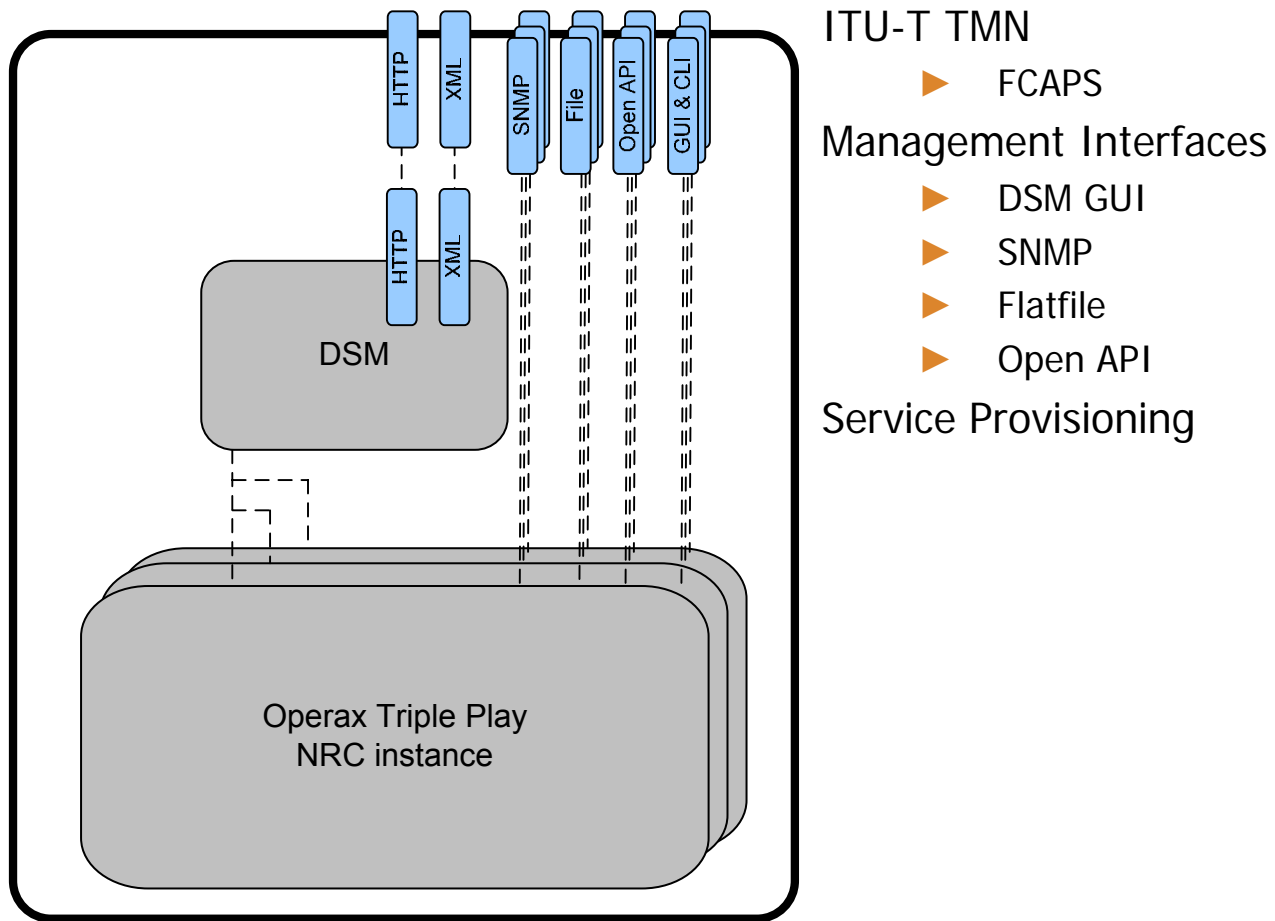

BGP Policies

- ▶ NRC conforms to advertisements (that might be result of configured policies in routers)

---

# Operation and Maintenance

# Operation and Maintenance

## Distributed System Manager (DSM)

---

Centralized installation, configuration and management of Operax systems

Integration with management systems via

- ▶ Web interface that supports
  - Basic administration task
  - Remote management and software configuration
  - Installations, upgrades, configurations and backups
  - Inventory reports and status information about the installations
- ▶ XML interface that supports
  - More advanced system-to-system integration tasks

## Summary of values

---

### **New services and business models**

- ▶ Speed to market (voice, video, data, etc)

### **Increased network efficiency**

- ▶ Flexible cross-service resource sharing
- ▶ QoS across contention points

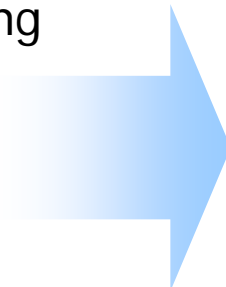

### **Increased operational efficiency**

- ▶ Reduced MPLS provisioning
- ▶ Feedback to provisioning process

### **Reduced capital expenditures**

- ▶ Multi-vendor networks

### **End-to-end QoS**

Maximized network utilization

Increased return on made investments

Increased revenues

Reduced operational overhead

Reduced capital expenditure
