

# EUROS

## Feature D “Multicast Middleware”

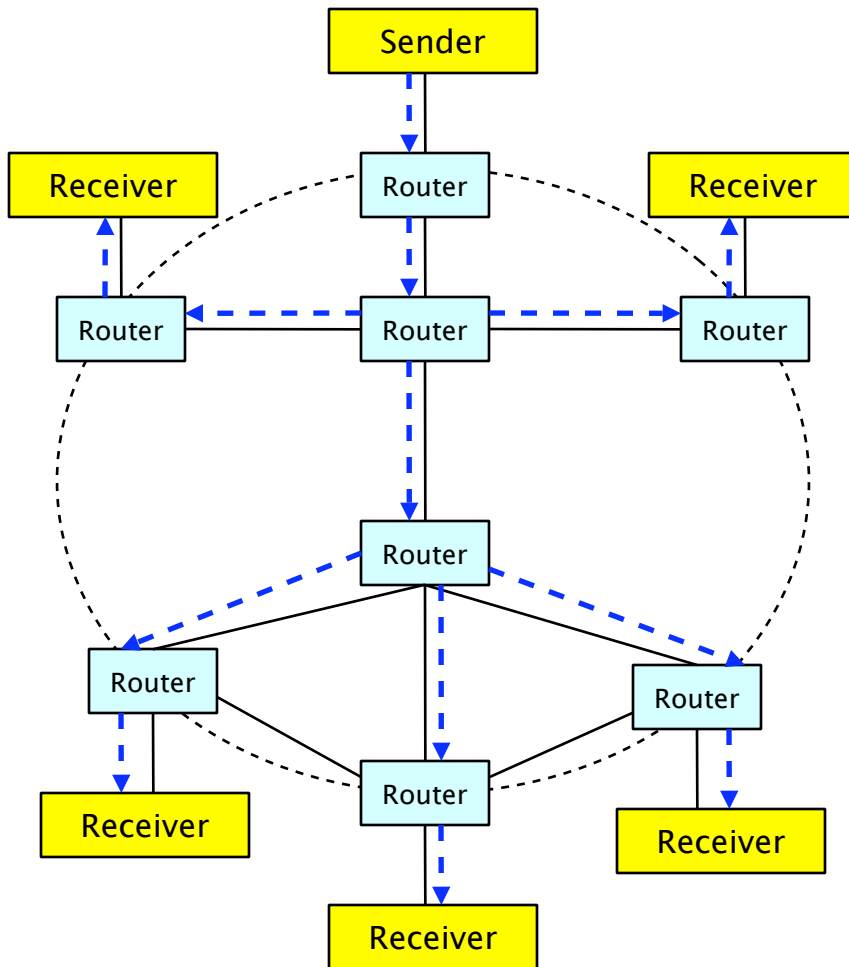

### Architecture Overview and Demonstration

- Multicast in EUQoS
- Traditional multicast vs. overlay multicast
- Features
- Demo setup
- Functional overview
- Demo
- Multicast Middleware interfaces
- Multicast routing protocol and overlay setup
- Open tasks

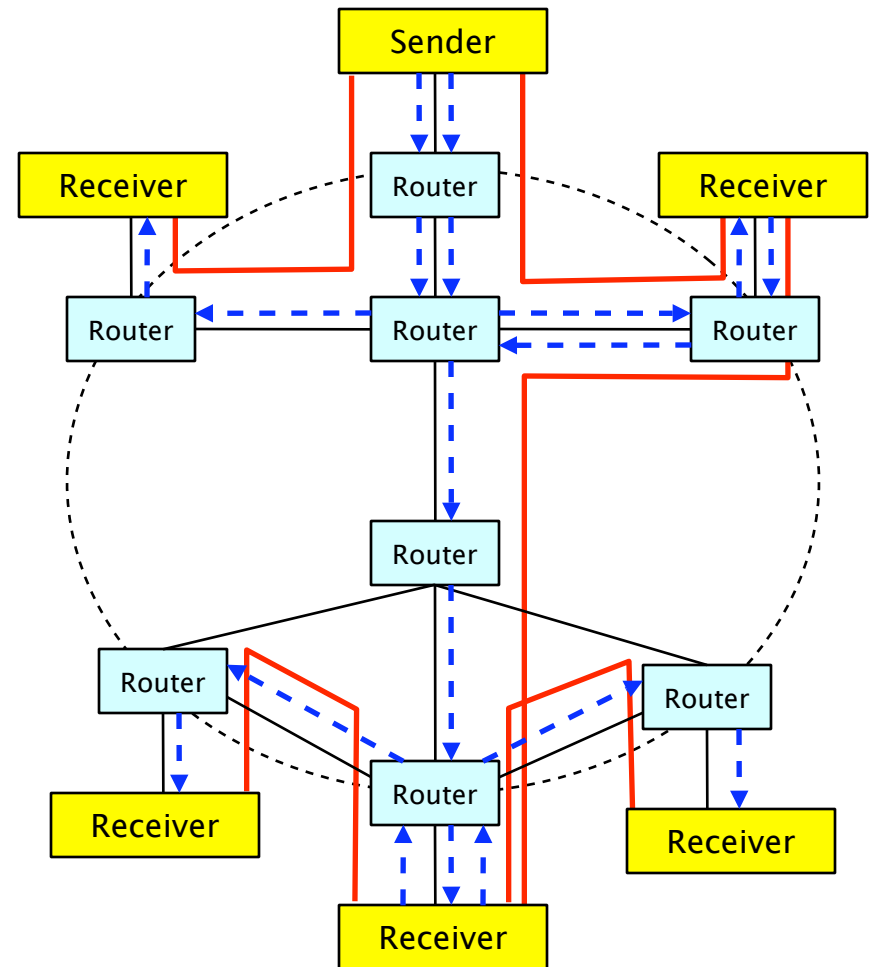

- Since “native” multicast is not widely deployed in the Internet, it is necessary to emulate multicast by using unicast communication
- Overlay (peer-to-peer) networks allow data dissemination (multicasting) with an approximation of the “native” multicast efficiency using only unicast communication
- Overlay multicast infrastructures can be made transparent for end-users by tunneling “real” multicast packets through an overlay structure

# Traditional Multicast vs. Overlay Multicast

Multicast

Overlay Multicast

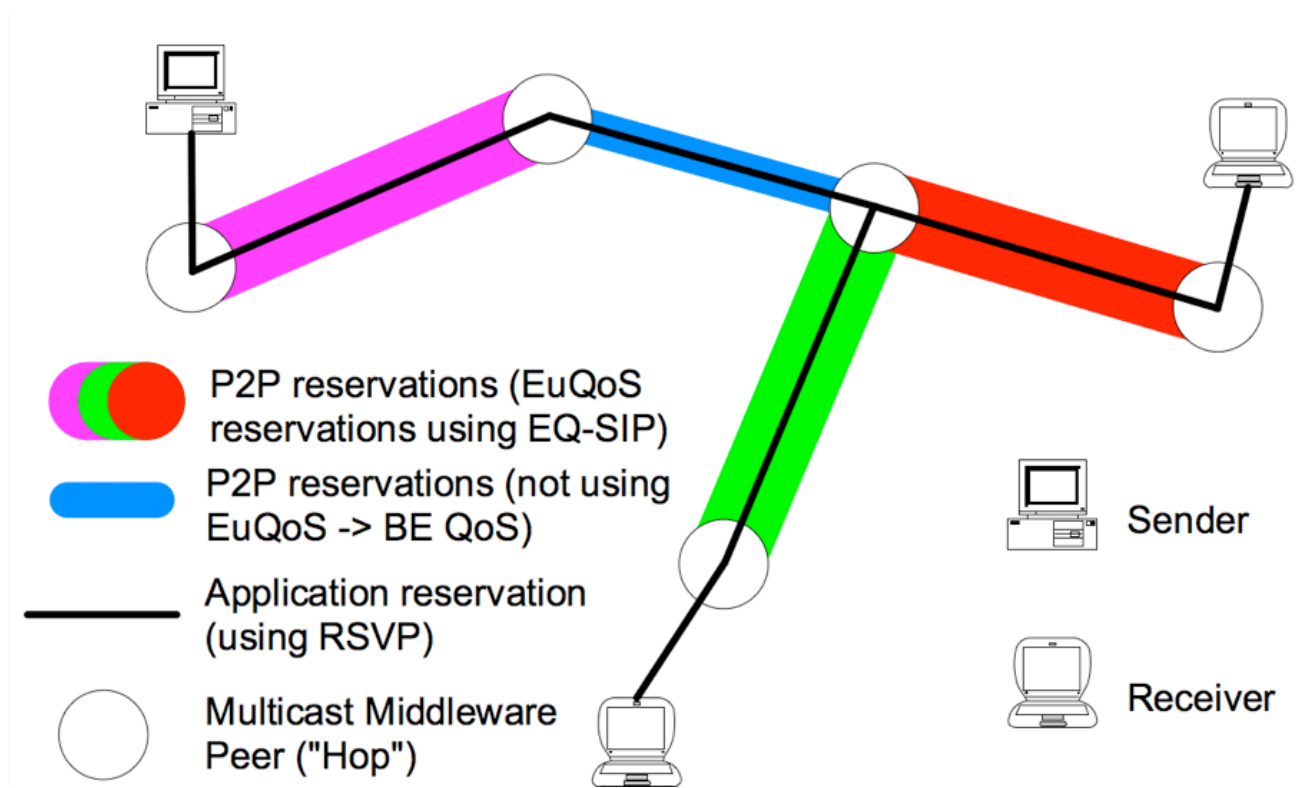

← - - Multicast Packet Flow

— Physical Link

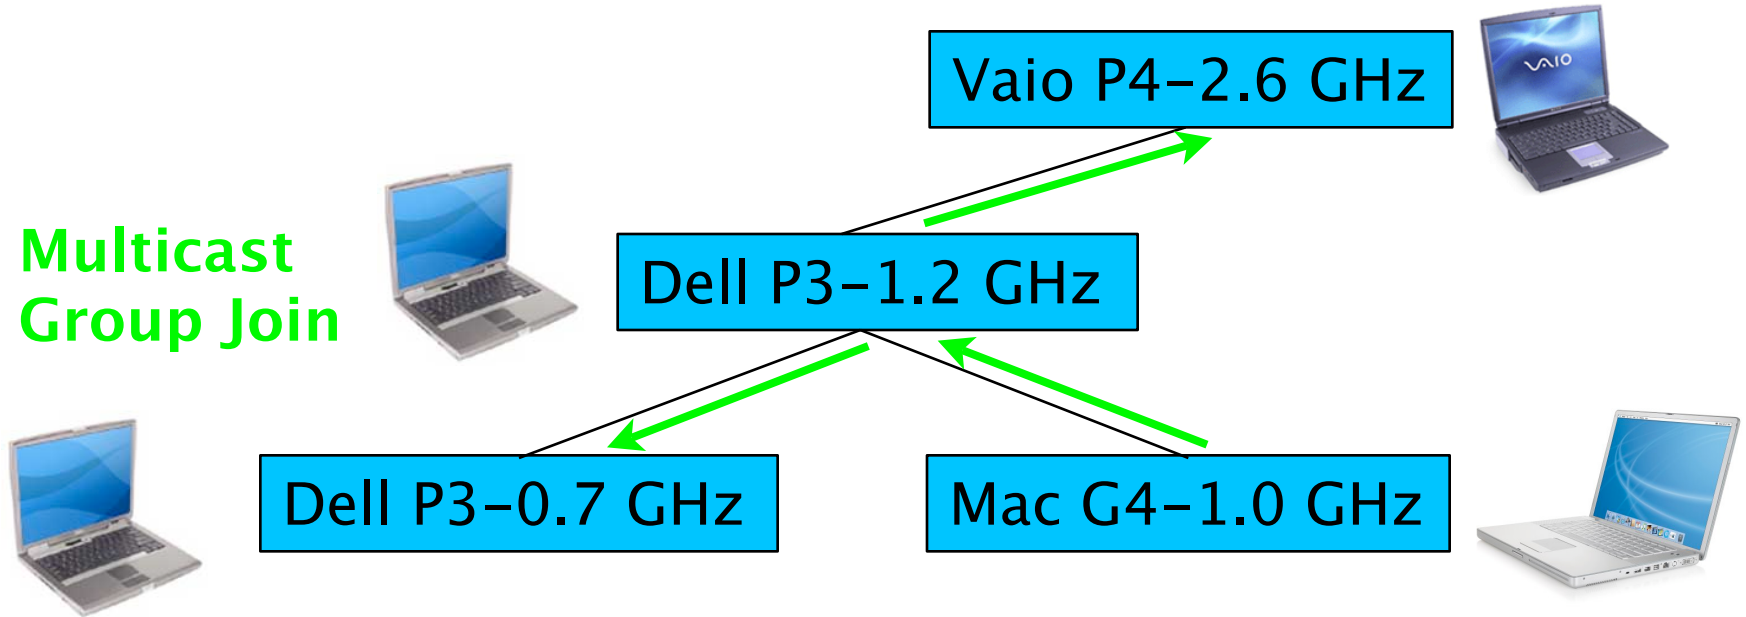

— P2P Link

- “Multicast Middleware” enables multicast (with QoS support) on end systems across the Internet using only unicast communication
- A P2P network transports multicast payload
- Transparent for the host system applications
- Requires no additional infrastructure
- Supports EUQoS QoS-signaling
- Supports measurement based “Best Effort” QoS admission control in absence of other reservation mechanisms

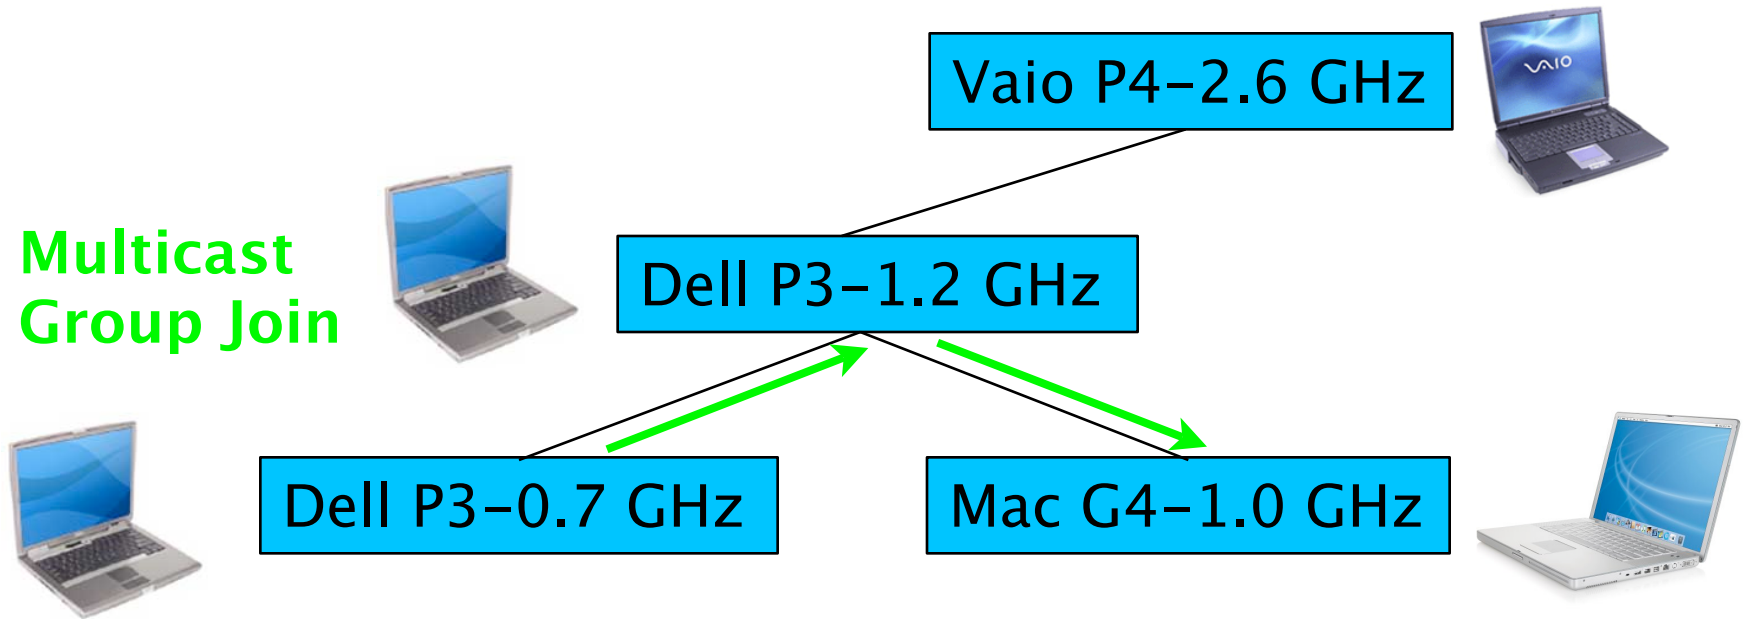

- EUQoS QoS reservation combined with “BE”-QoS (measurement based) reservation

## Multicast Group Join

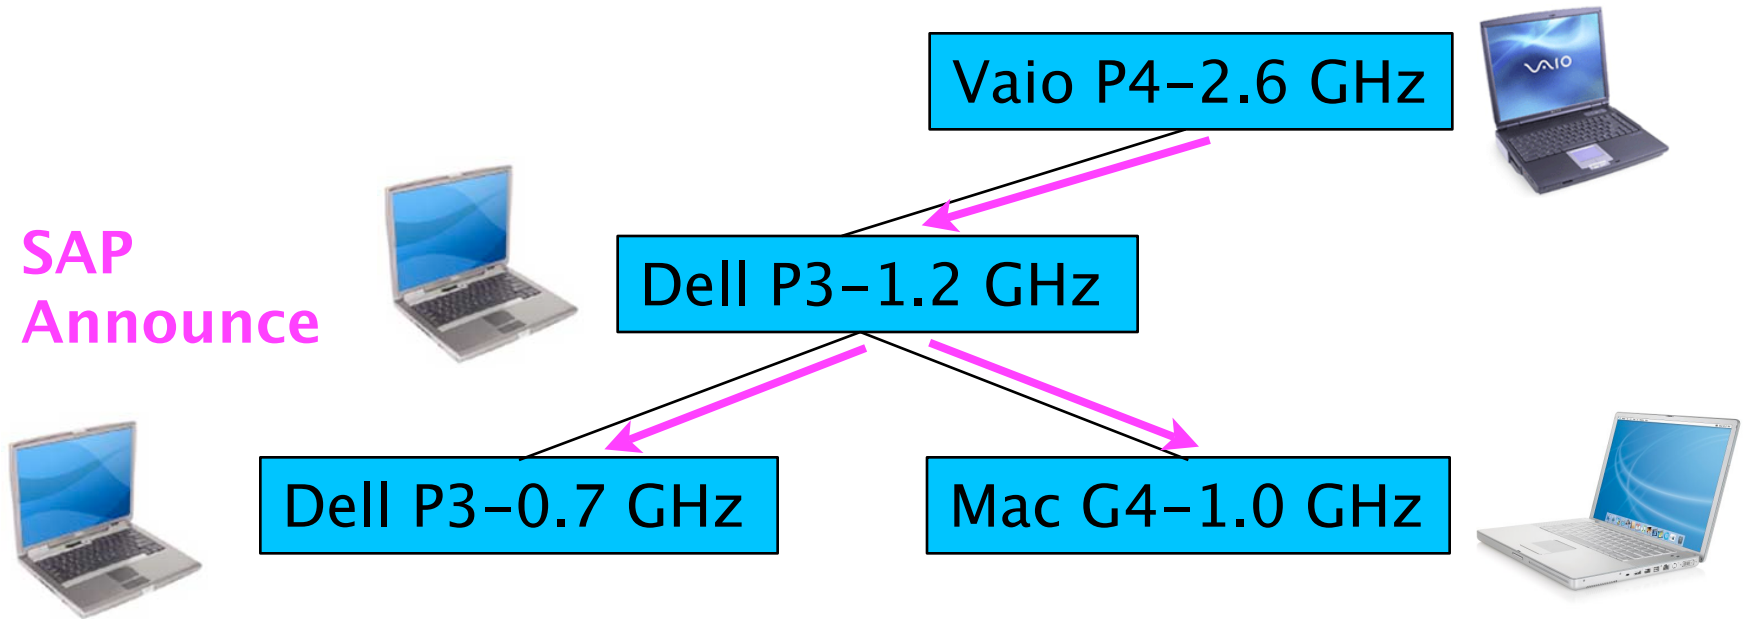

- Media: VCD MPEG-TS 1.4 Mbit/s
- Applications: VLC (built-in multicast support)
- Technologies: Java 1.5, tun/tap
- Protocols: UDP, TCP, IGMP, SAP

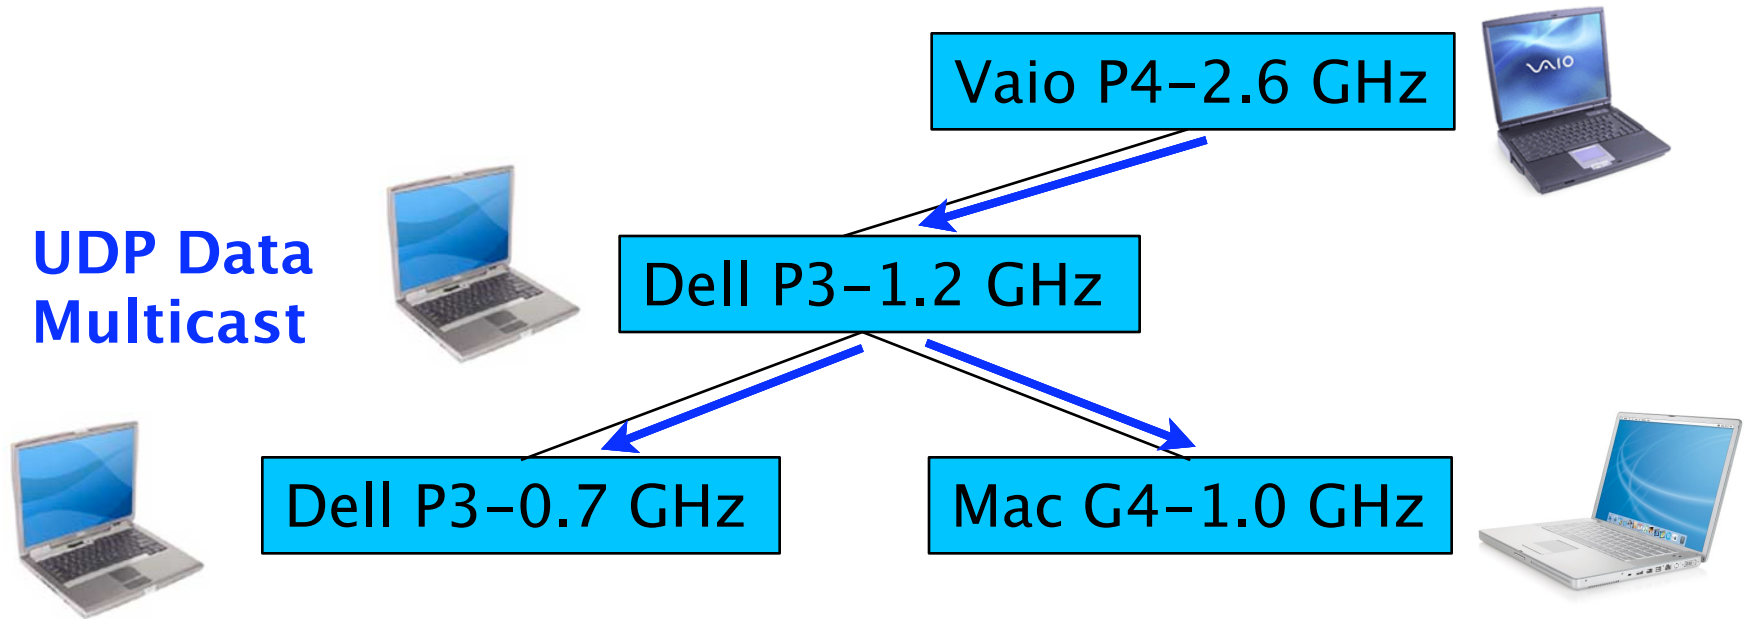

- Media: VCD MPEG-TS 1.4 Mbit/s
- Applications: VLC (built-in multicast support)
- Technologies: Java 1.5, tun/tap
- Protocols: UDP, TCP, IGMP, SAP

- Technologies: Java 1.5, tun/tap
- Protocols: UDP, TCP, IGMP, SAP

## ■ 1 a. IGMP

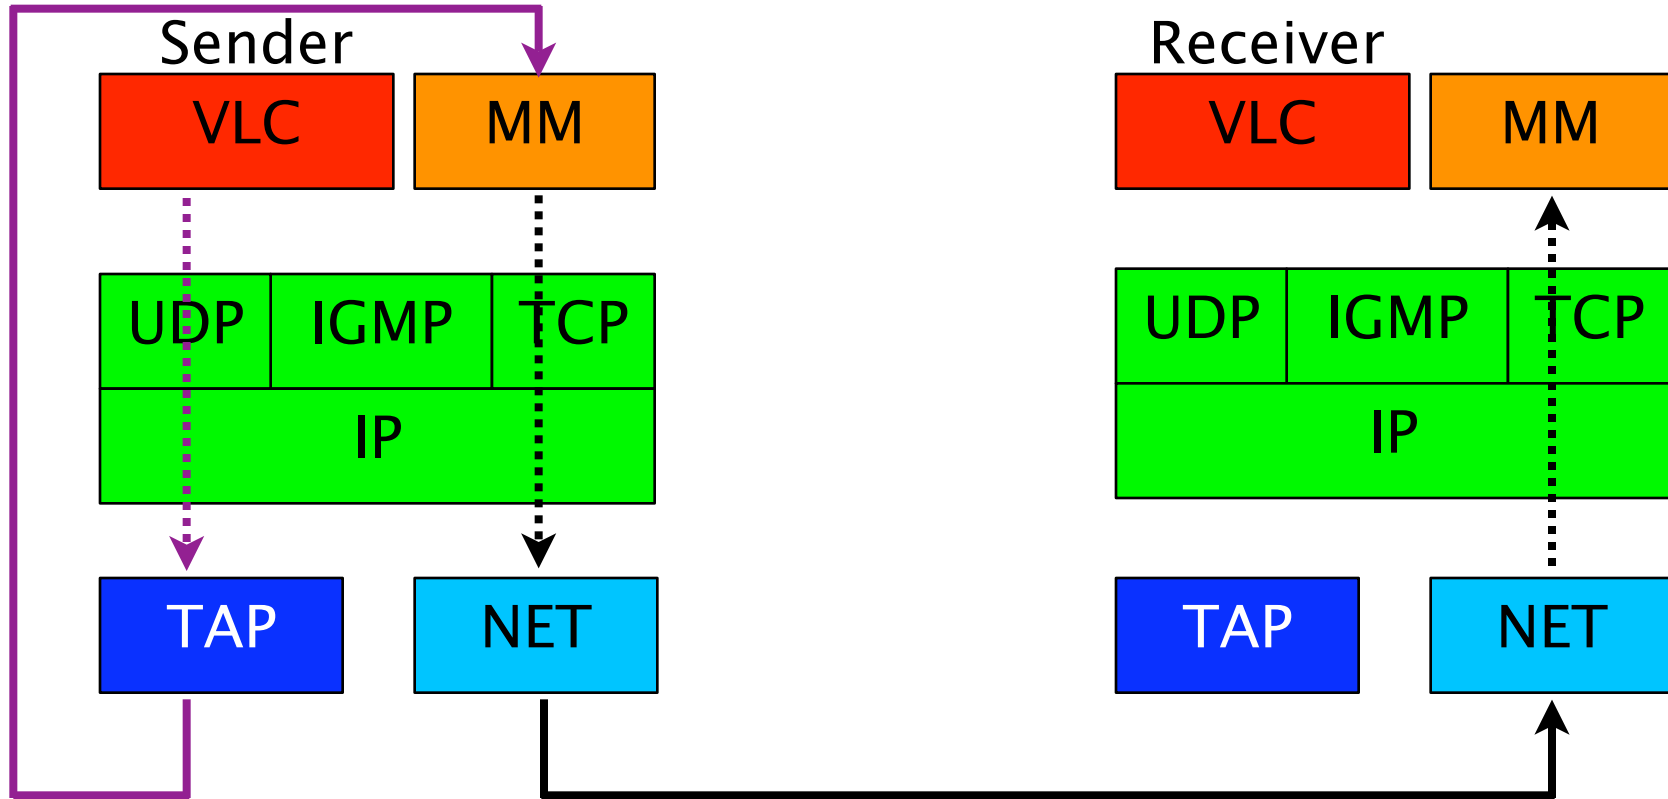

## ■ 1 b. P2P Add Route Message

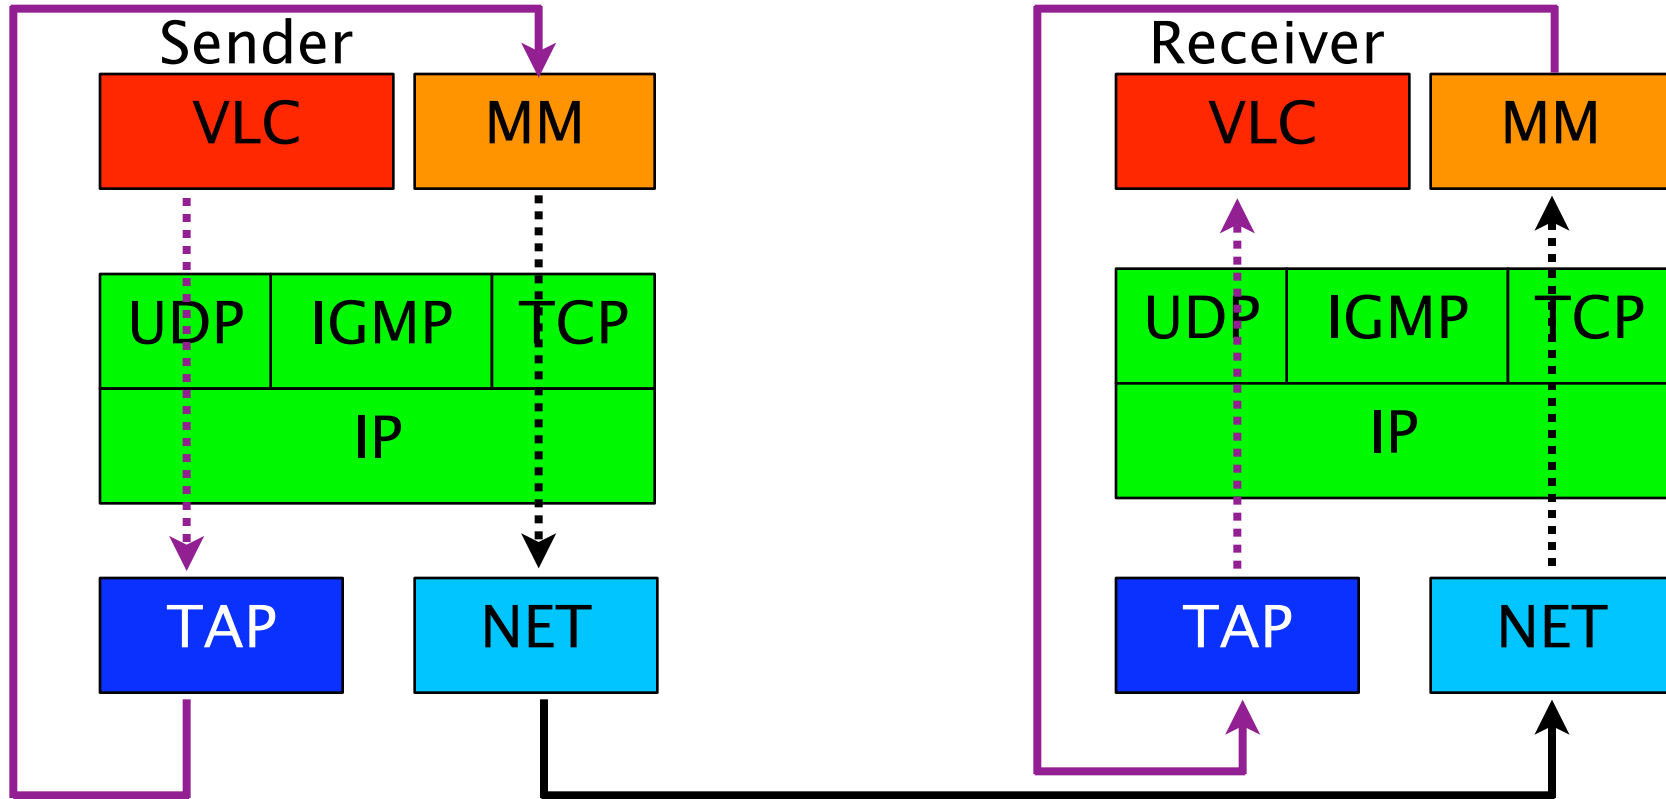

## ■ 2a. UDP Data

## ■ 2b. P2P Data Message

## ■ 2c. UDP Data

- Transparent interface for the multicast applications using a tun/tap device
- RSVP based reservation QoS signaling for legacy applications
- Web-based user interface for management
- Webservices-based reservation interface for EUQoS-aware local applications
- Webservices-based management facility for EUQoS modules
- Webservices-based MMFM functionality

- Current routing protocol
  - Sets pro-actively routes towards all receivers (in worst case: flooding of the overlay network for every group join)
  - Does not scale well
  - Found routes are optimal regarding hop count
  - Sufficient approach for current implementation
  - It works only with acyclic, tree-like topologies
- Overlay setup
  - Manual (configuration file) setup of P2P-links
  - Should be replaced by a more intelligent P2P setup algorithm based on net conditions / measurements

- Improving the multicast routing protocol
- Improving the overlay bootstrapping and construction protocol
- Implementing native (OS-specific) forwarders to improve performance
- Implementing the reservation signaling and reservation of the unicast P2P-links
- Implementing the Web-based user interface
- Implementing the Webservice-based interfaces for EUQoS aware applications and modules
